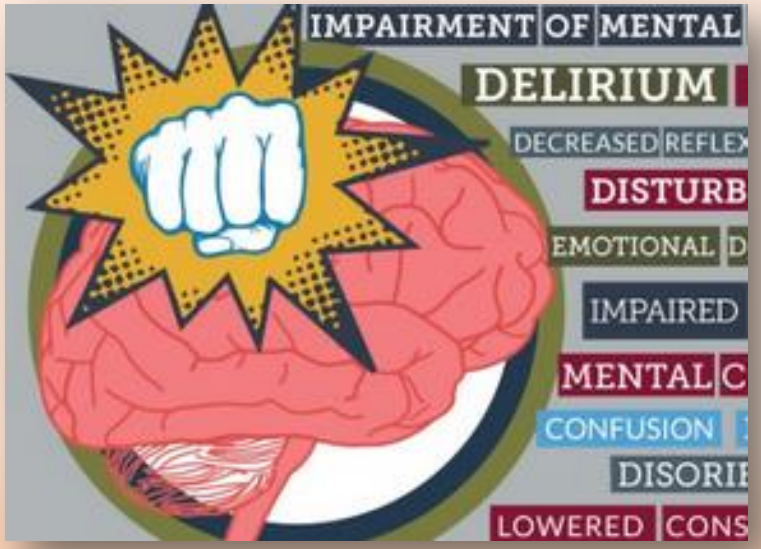
Cognitive Effects After ECT

- Immediate, after each ECT session
- Subacute and longer-term, during and after completing an ECT course
- Retrograde autobiographical amnesia

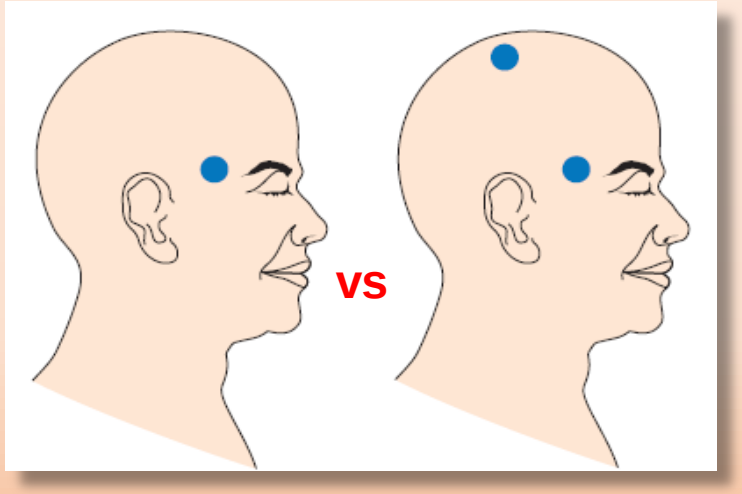


EFFECT-Dep Trial

Enhancing the Effectiveness of ECT in Severe Depression

ISRCTN23577151

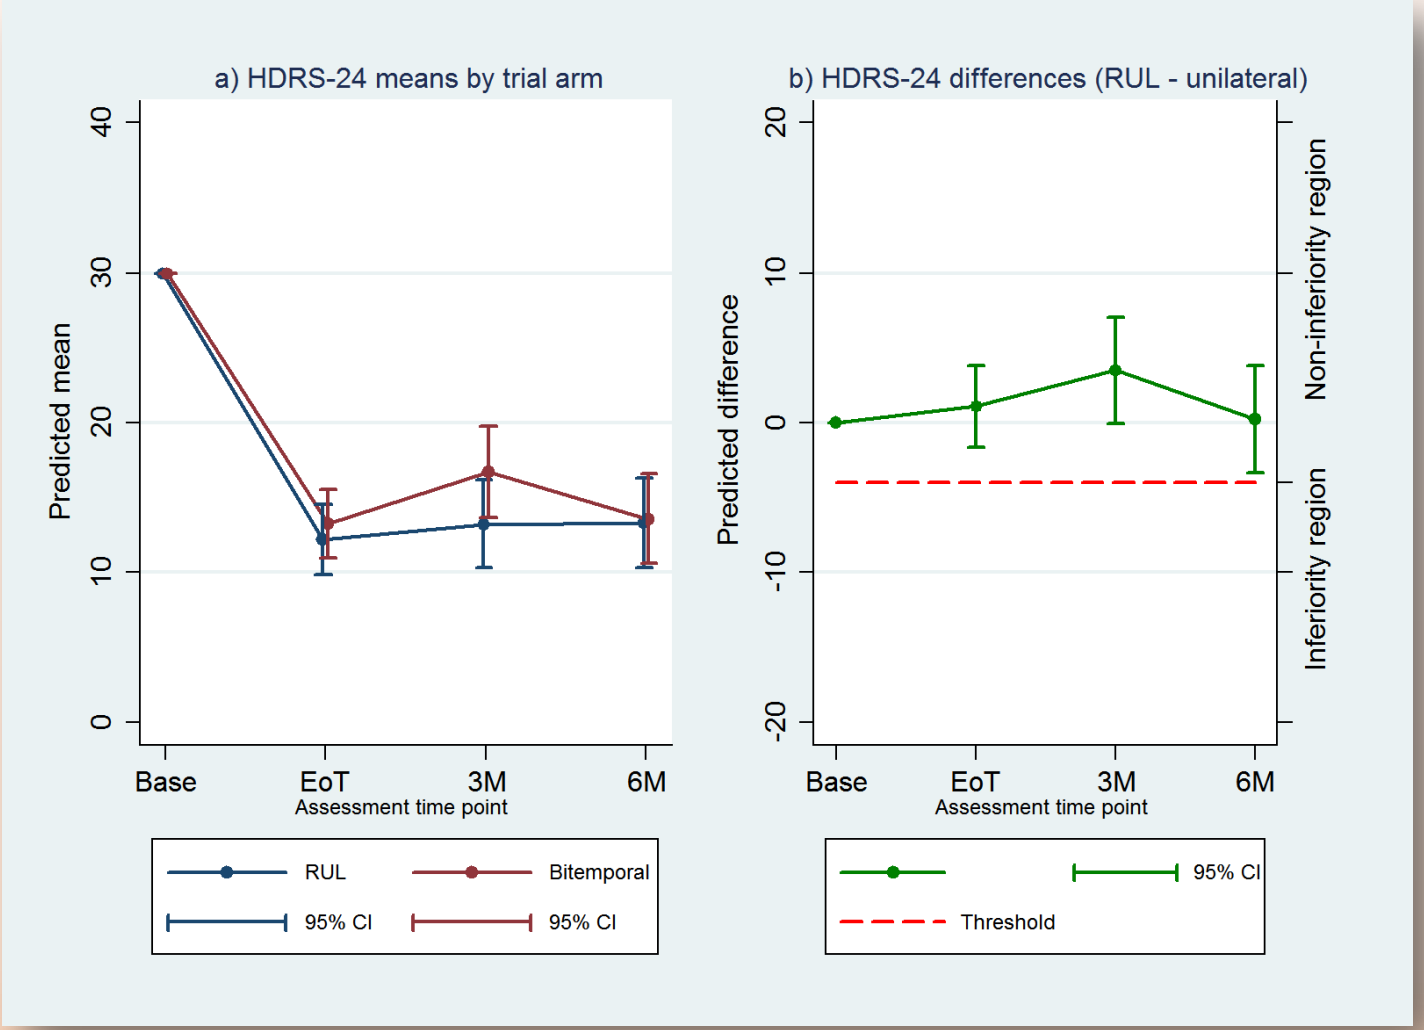
OBJECTIVE: to perform a pragmatic, randomised, non-inferiority trial comparing standard bitemporal ECT (1.5 x ST) and high-dose unilateral ECT (6 x ST) in severe depression in routine practice



Semkovska *et al.*, 2016 *Am J Psychiatry* 173:408-417

Primary outcome: HDRS-24

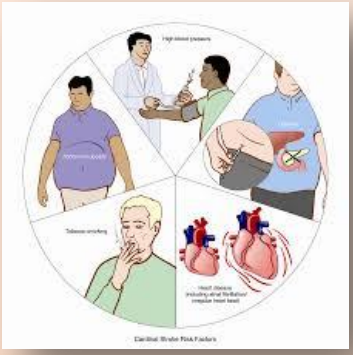
Mean HDRS estimated to be 1.2 points higher in the Bitemporal group; 95% CI, -1.510 to 3.995,
i.e. within the non-inferiority threshold.



Immediate cognitive effects of ECT

Disorientation: transient, but sometimes → Delirium

- Reorientation speed correlated with later retrograde amnesia (as was impaired pre-treatment cognition) (Sobin et al., 1995; Martin et al., 2015)
- Delayed reorientation associated with:
  - deep white matter abnormalities on MRI (Coffey et al., 1987; Figiel et al., 1990)
  - older age, longer seizure duration, bilateral electrode placement and greater number of treatments (Daniel and Crovitz, 1982; Calev et al., 1991; Kellner et al., 2010)
- TRD associated with deep white matter changes on MRI (Coffey et al., 1990; Simpson et al., 1998)
- Framingham Stroke Risk Score (FSRS) correlates with deep white matter changes on MRI brain in middle-aged populations (Jeerakathil et al., 2004)
- Such risk factors are also predictors of cognitive decline (Swan et al., 1998; Novak and Hajjar, 2010) and therefore may be markers for decreased cognitive reserve in vulnerable populations.



Observational study: reorientation time

PATIENTS

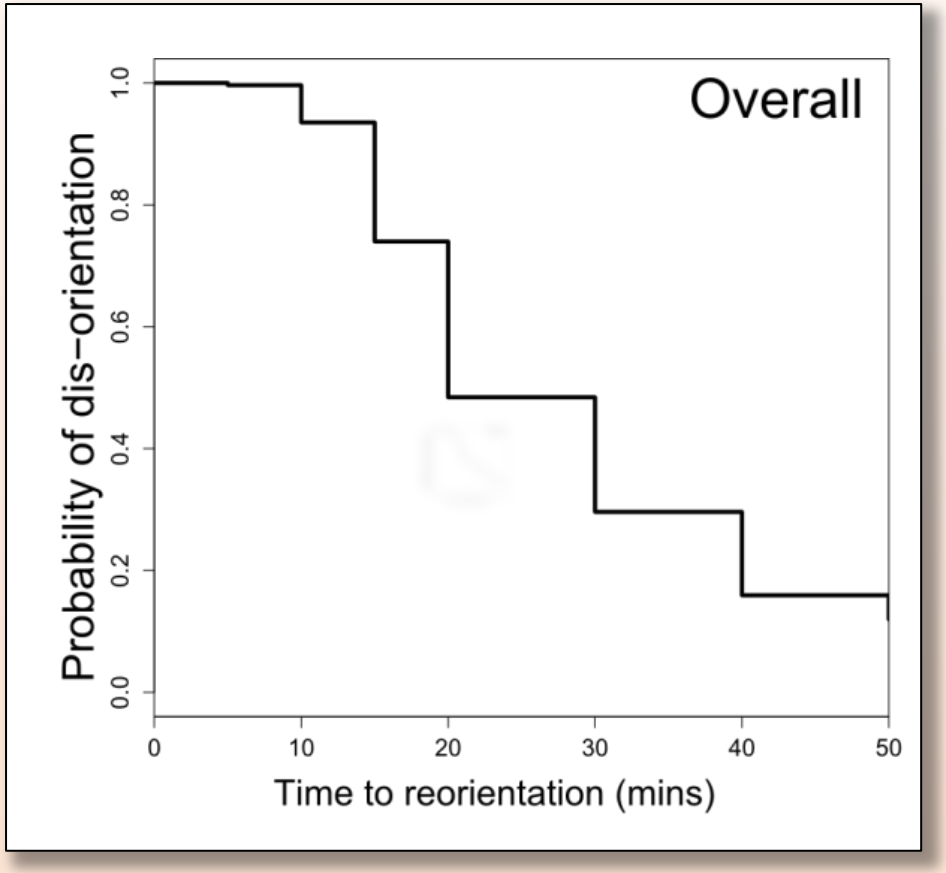
- 1,110 ECT treatments
- 149 courses of bitemporal ECT
- 129 patients
- reoriented if 4/5 items correct

RESULTS

Reorientation time >50 mins:

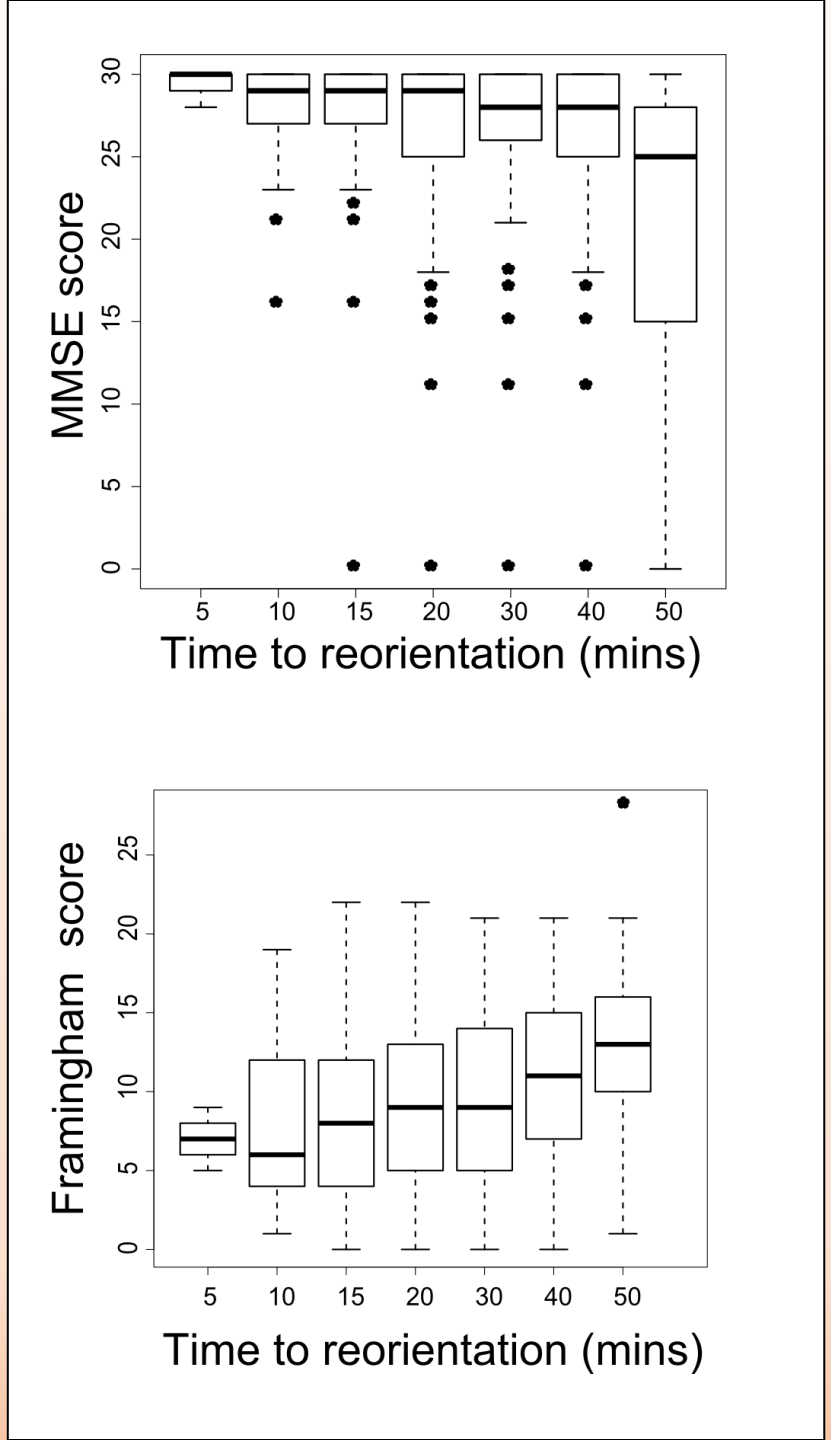
- 132(12%) of treatments
- 45(30%) of ECT courses
- 43(33%) of patients

74% ≤4 episodes
18% 5-6 episodes
7% 7-10 episodes



Kaplan-Meier survival curve for reorientation time

Boxplots of
(A) MMSE and
(B) FSRS versus re-orientation time.



Results – summary of analyses*

• **Higher FSRS scores** ↑ed reorientation time, each additional 5 points reducing instantaneous reorientation probability by 25% (95%CI, 5-40%; P<.001). [**Note**: Age and education less informative than FSRS; no r'ship with CGI change score]

• **Higher pre-ECT MMSE scores** predicted faster full reorientation, each additional point increasing probability 4% in the multivariate model (p<.001)

• **Lithium** ~60% less likely to answer each question at each time point (OR=.41; 95% CI, .2-.8; P=.007), the effect waning with time (OR=1.15; 95%CI,1.1-1.2; P<.001). [**Note**: no effect in univariate model]

****

• **Each additional 10s of EEG seizure** decreased instantaneous probability of full reorientation by 10% at each timepoint (95% CI, 9-11%; P<.001)

• Cumulative effect, **with each treatment** decreasing probability of reorientation at each timepoint by 10% (95%CI, 4-16; P<.01), despite shortening seizures.

*Ordinal logistic mixed-effects regression with random terms for individuals, treatments and courses (*ordinal* in R); coefficients are exponentiated to produce odds ratios (OR).

EFFECT-Dep Trial

	RUL ECT (*n*=69)	Bitemporal ECT (*n*=69)	Formal test*
ECT treatment characteristics			
Anaesthesia*			
Methohexitone (mg/kg)	1·08 (0·20), *n*=67	1·02 (0·21)	NA

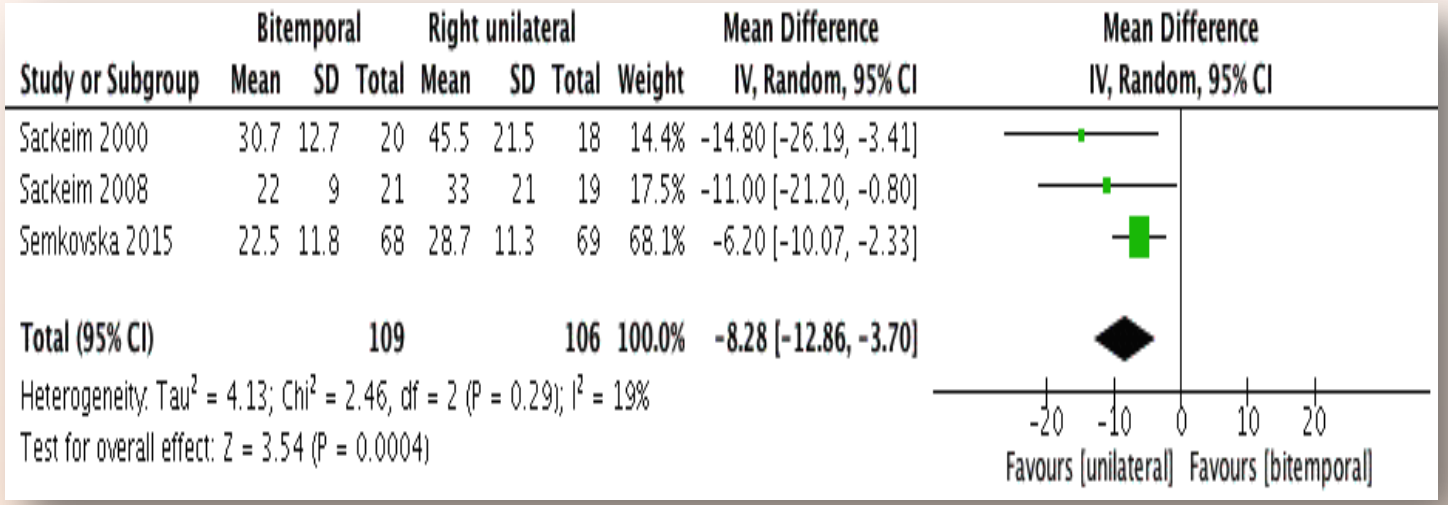
Recovery of orientation* [medians and ranges]**			
Time to recovery (mins), initial titration session	10 (5-60), *n*=68	20 (5-60)	*t*(130)=6·82, *p*<0·001**
Time to recovery (mins), non-titration sessions**	19·1 (10-55), *n*=68	26·4 (10-60)	*t*(130)= 3·88, *p*<0·001**

Data are expressed as means and standard deviation. *All models used to construct inferences conditioned on stratifiers. **Formal inferences carried out after log-transformation. NA=not attempted. mC=millicoulombs. EEG=electroencephalogram. ST=seizure threshold. *Six patients received propofol during their ECT course at standard doses due to temporary shortage of methohexital, four in the bitemporal group and two in the unilateral group. **Sessions following the definite establishment of ST. ***Recovery of orientation was defined as correctly answering 4/5 reorientation questions.

Table 2: ECT session measures

Meta-analysis of high-dose RUL vs BT ECT: Recovery of orientation



Forest plot of mean time (in minutes) to achieve reorientation after ECT treatments.

Kolshus, Jelovac, McLoughlin (2017) *Psychol Med*

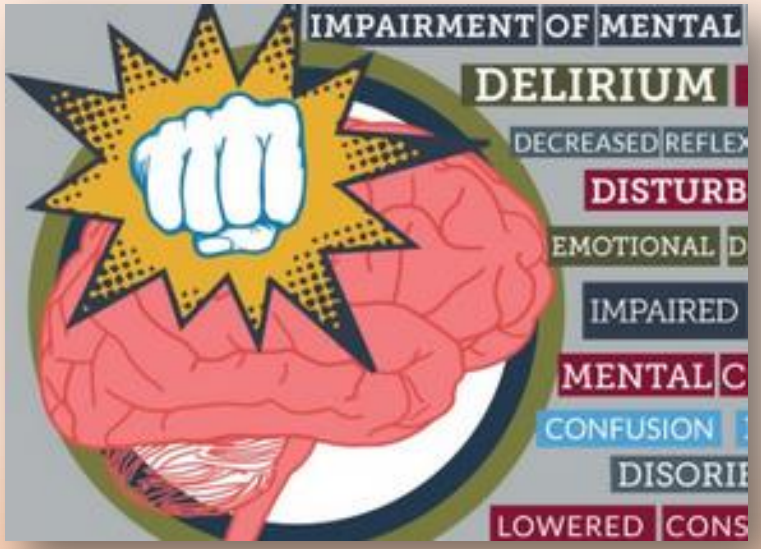
Summary: Recovery of orientation following ECT

- **Recovery retarded by:**
  - ***cardiovascular risk factors (e.g. FSRS)**
  - **lower MMSE score**
  - **longer EEG seizure duration**
  - **more treatments**
  - **Lithium (early disorientation <u>but</u> no effect on likelihood of full re-orientation)**

- **Recovery hastened by:**
  - **anti-epileptic medication**
  - **unilateral electrode placement**

Cognitive Effects After ECT

- Immediate, after each ECT session
- Subacute and longer-term, during and after completing an ECT course
- Retrograde autobiographical amnesia



Cognitive effects of ECT: subacute and longer term

Cognitive effects of ECT in depression: a meta-analysis

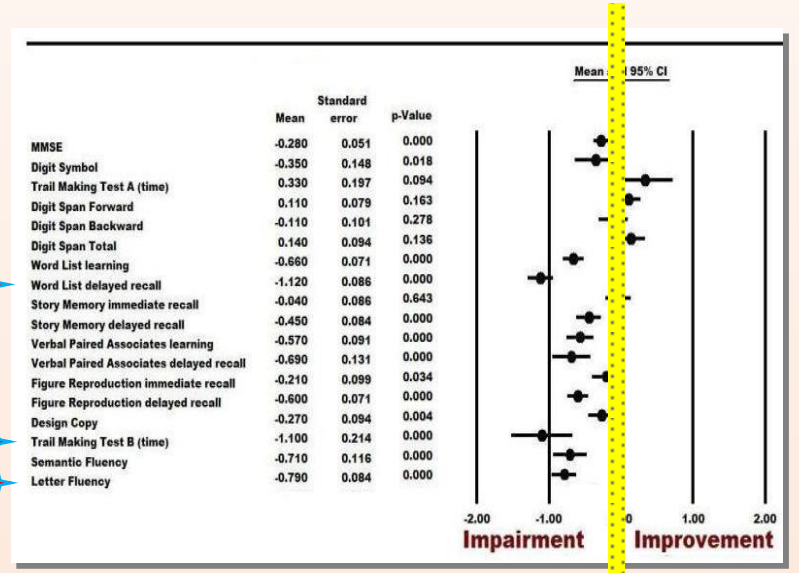
- A wide range of **memory and non-memory** cognitive impairments, as measured by *standardised tests*, are evident after end of treatment.

- Afterwards, most cognitive functions improve beyond baseline.

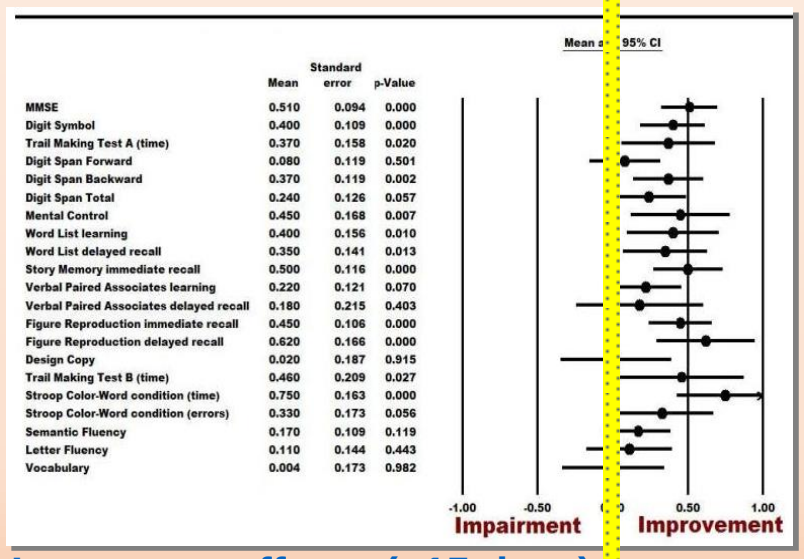
- Differences in ECT techniques, parameters or patient characteristics contributed mainly to short-term effects.

- Unable to include retrograde memory.

- Need to consider depression severity and residual symptoms; medications; type of ECT



Sub-acute effects (0-3 days)



Long-term effects (>15 days)

Semkovska & McLoughlin (2010), *Biological Psychiatry*

Subacute and longer-term cognitive outcomes

FCSRT: immediate verbal recall

- EOT: est difference=-3.1, p=0.043*
- 3 mths: no significant difference
- 6 mths: no significant difference

Digit span forward (attention)

- EOT: est difference=-0.69, p=0.11
- 3 mths: est difference=-1.17, p=0.015*
- 6 mths: est difference=-0.87, p=0.08

No difference between groups at any time point for:

- MMSE (global cognition)
- Digit span backwards (working memory)
- Trail making test A (processing speed)
- Trail making test B (executive function)
- Category fluency (executive function)
- Rey delayed recall (visual episodic memory)
- FCSRT delayed recall (verbal episodic memory)

EFFECT-Dep Trial

Enhancing the Effectiveness of ECT in Severe Depression

TABLE S4: Results of analyses of cognitive outcomes by post treatment time point						
Cognitive tasks			Comparison of randomisation groups[a]

6 months	9.6 (N=32)	9.2 (N=28)	-0.4	-1.8 to 1.05	-0.53	0.60

Q: What is the nature and pattern of cognitive change post-ECT?

A: Some decline followed by recovery and maybe a "general" trend for improvement

EFFECT-Dep Trial

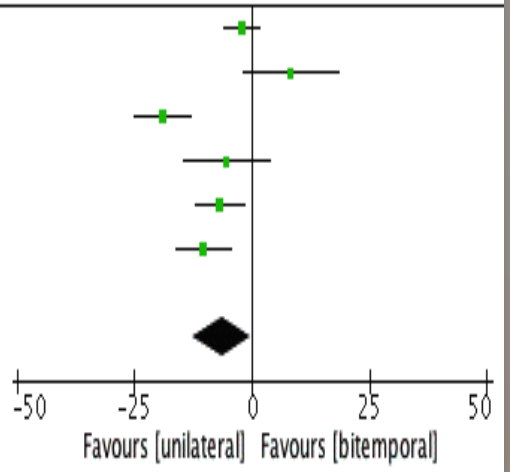
Total (95% CI)			**304**			**313**	**100.0%**	**-6.50 [-12.78, -0.21]**

Heterogeneity: $Tau^2 = 49.78$; $Chi^2 = 32.05$, df = 5 ($P < 0.00001$); $I^2 = 84\%$

Test for overall effect: Z = 2.03 (P = 0.04)



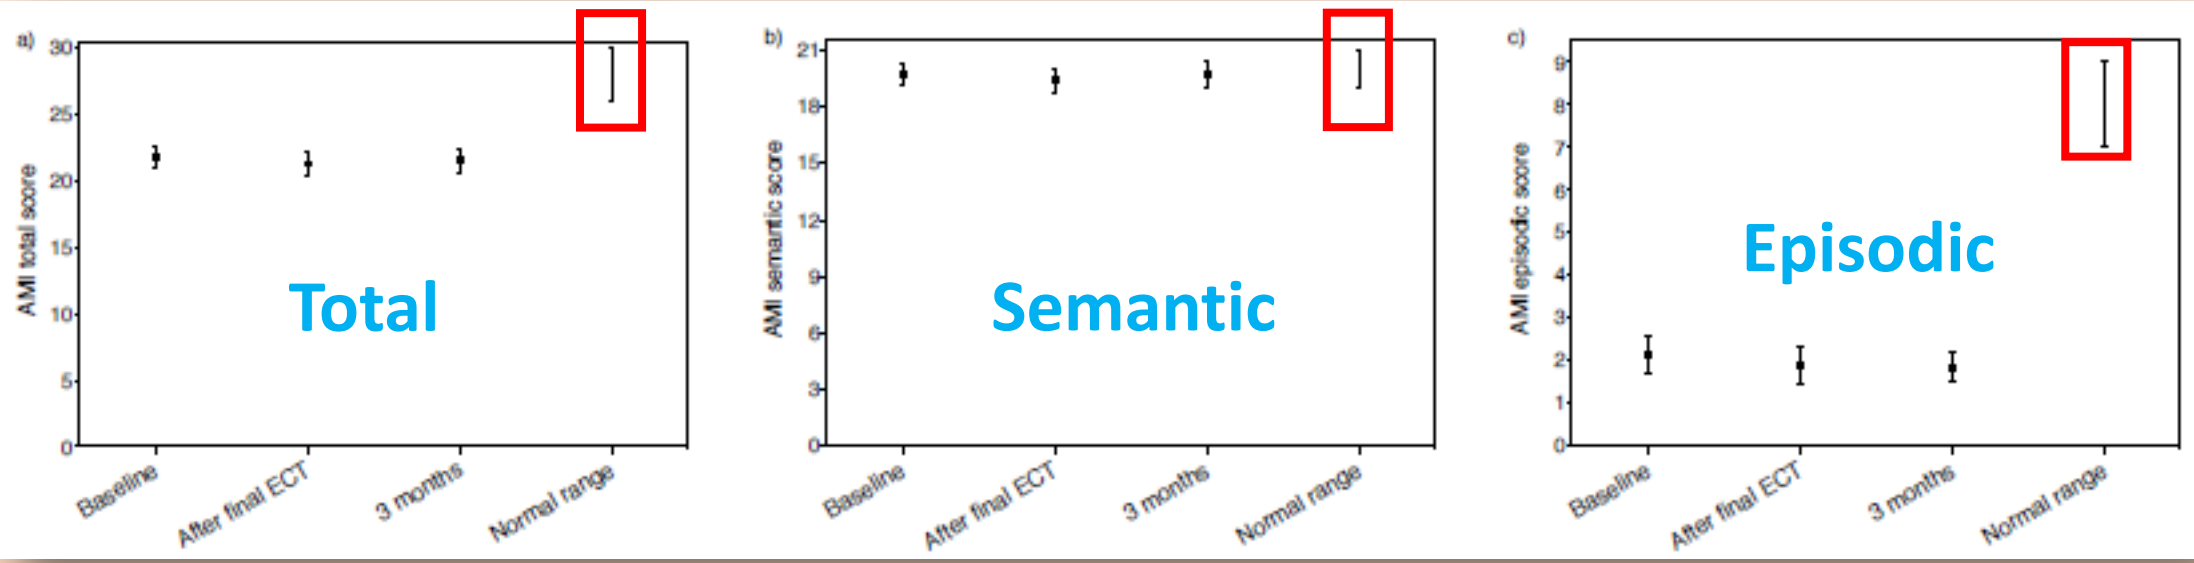
Forest plot of retrograde amnesia (as % of baseline) for autobiographical memory (CAMI-SF) at end of treatment.

Kolshus, Jelovac, McLoughlin (2017) *Psychol Med*

Cognitive effects of ECT: Kopelman AMI - recent

- N=48 depressed pts (mean age, 61.6; female, 62.5%) having bitemporal ECT
- "Recent Life" section of the Kopelman Autobiographical Memory Interview (AMI)
- 77% response rate
- no significant changes over time on either AMI total score or semantic and episodic subscales. However, patients were markedly impaired on episodic autobiographical memory compared with the normative sample at all 3 assessment points, whereas personal semantic memory recall was normal.

- **Does this mean that there is no retrograde amnesia?**



Jelovac et al (2016) *J ECT*

Kopelman AMI – Childhood, Early Adult Life, and Recent Life

KEEP WELL

Cases vs Controls

- Balanced for age and sex
- Controls had higher IQ
- Slightly better educated
- Similar socioeconomic status

Gusciete et al (2018) *MSc thesis*

Risk factors for cognitive deficits

Patient-related

- Old age
- Diminished cognitive reserve
- Existing brain disease

Treatment-related

- Concomitant psychotropic agents, e.g. lithium
- Higher anaesthetic dose, ?anticholinergics
- Bitemporal ECT
- High-dose ECT
- Sine wave ECT
- Greater pulse-width
- Greater frequency of ECT
- Greater number of treatments
